

After a local rain storm, your news station might announce that 0.5 inches of rain fell during the morning hours before Noon.

Have you ever wondered just how much water fell out of the sky to cause so much trouble to people trying to get to work or stay dry outside?

Meteorologists classify rain rates for different levels of activity as you can see in the table below:

| Type of Storm | Rate |
| :---: | :---: |
| Light Rain | $2-4 \mathrm{~mm} / \mathrm{hr}$ |
| Moderate | $5-9 \mathrm{~mm} / \mathrm{hr}$ |
| Heavy | $10-40 \mathrm{~mm} / \mathrm{hr}$ |
| Violent | more than $50 \mathrm{~mm} / \mathrm{hr}$ |

Problem 1 - Suppose the local news said that 1.6 inches of rain fell between 8:00 am and 1:00 pm. What type of storm was this? ( 1 inch $=25 \mathrm{~mm}$ )

Problem 2 - If 1 mm of rainfall equals 1 liter of water over an area of one square meter, how many liters of water will fall over a town that has an area of $100 \mathrm{~km}^{2}$ during a light rain shower that lasted 3 hours at a rate of $2 \mathrm{~mm} / \mathrm{hr}$ ?

Problem 3 - About 500,000 cubic kilometers of rain falls on the surface of Earth every year. What is the average rate in $\mathrm{mm} / \mathrm{hr}$ if the surface area of Earth is 500 million $\mathrm{km}^{2}$ ?

## Common Core Math Standards:

Grade 6 - CCSS.Math.Content.6.RP.A.3b Solve unit rate problems including those involving unit pricing and constant speed. For example, if it took 7 hours to mow 4 lawns, then at that rate, how many lawns could be mowed in 35 hours? At what rate were lawns being mowed?

Grade 7 - CCSS.Math.Content.7.RP.A. 1 Compute unit rates associated with ratios of fractions, including ratios of lengths, areas and other quantities measured in like or different units. For example, if a person walks $1 / 2$ mile in each $1 / 4$ hour, compute the unit rate as the complex fraction 1/2/1/4 miles per hour, equivalently 2 miles per hour.

Optional: Grade 8 - CCSS.Math.Content.8.EE.A. 4 Perform operations with numbers expressed in scientific notation, including problems where both decimal and scientific notation are used. Use scientific notation and choose units of appropriate size for measurements of very large or very small quantities (e.g., use millimeters per year for seafloor spreading). Interpret scientific notation that has been generated by technology

Problem 1 - Suppose the local news said that 1.6 inches of rain fell between 8:00 am and 1:00 pm. What type of storm was this? ( 1 inch $=25 \mathrm{~mm}$ )

Answer: The depth of the rain was 1.6 inches $\times 25 \mathrm{~mm} / 1 \mathrm{inch}=40 \mathrm{~mm}$. This fell in the time between 8:00 am and 1:00 pm which is 5 hours, so the rate was $40 \mathrm{~mm} / 5$ hours $=8 \mathrm{~mm} / \mathrm{hr}$. This type of storm would be considered a moderate storm.

Problem 2 - If 1 mm of rainfall equals 1 liter of water over an area of one square meter, how many liters of water will fall over a town that has an area of $100 \mathrm{~km}^{2}$ during a light rain shower that lasted 3 hours at a rate of $2 \mathrm{~mm} / \mathrm{hr}$ ?

Answer: First we have to calculate the total number of millimeters that fell, which is $2 \mathrm{~mm} / \mathrm{hr} \mathrm{x}$ 3 hours or 6 millimeters.

Then we calculate the rate in terms of liters $/$ meter $^{2}$ which will be $6 \mathrm{~mm} \times\left(1\right.$ Liter $/$ meter $\left.^{2}\right)=6$ Liters/meter ${ }^{2}$.

Next we convert the area of the town into square meters, which is $100 \mathrm{~km}^{2} \times(1000 \mathrm{~m} / 1 \mathrm{~km}) \mathrm{x}$ $(1000 \mathrm{~m} / 1 \mathrm{~km})=10^{8}$ meters $^{2}$.

Finally we multiply the rate by the area to get 6 liters $/$ meter $^{2} \times 10^{8}$ meters $^{2}=\mathbf{6 . 0 \times 1 0 ^ { 8 }}$ Liters.

Problem 3 - About 500,000 cubic kilometers of rain falls on the surface of Earth every year. What is the average rate in $\mathrm{mm} / \mathrm{hr}$ if the surface area of Earth is 500 million $\mathrm{km}^{2}$ ?

Answer: Volume $=$ Height $\times$ Area so
$500,000 \mathrm{~km}^{3}=$ height $\times 500$ million $\mathrm{km}^{2}$ and so
height $=500,000 / 500,000,000=1 / 1000 \mathrm{~km}$ or 1 meter.
This falls in one year. 1 year $=365$ days $\times 24 h / 1$ day $=8760$ hours so the rate is
$\mathrm{R}=1$ meter/8760 hours
$=1000 \mathrm{~mm} / 8750 \mathrm{hrs}$
$=0.11 \mathrm{~mm} / \mathrm{hr}$.
